TITLE: Electronographic and roentgenographic investigation of substructure of thin nickel and iron films condensed in vacuum

SOURCE: Fizika metallov i metallovedeniye, v. 17, no. 5, 1964, 726-731

TOPIC TAGS: nickel, iron, thin film, vacuum condensation, electronographic analysis, x ray analysis, gold, aluminum, silver, electronograph EG, diffractometer URS 50Im, metal film substructure, elasticity limit

ABSTRACT: Thin nickel and iron films precipitated in vacuum were investigated to compare their structures to those of gold, aluminum, and silver. The samples consisted of metal films 200 Å thick condensed on unheated base plates. These plates were made of glass and of NaCl crystals. Some films were precipitated on thin collodion films. Samples prepared in the above way were analyzed in transient light in the electronograph EG. The x-ray study was performed with a diffractometer URS-50Im. For this purpose, samples consisting of 30 overlying films were prepared.

Card 1/2

ACCESSION NR: APl4039600

The results obtained by these two methods supplemented each other because the x-ray analysis revealed substructural characteristics in the direction perpendicular to the film surface, while the electronographic analysis showed them in the direction parallel to the surface. Average linear size of the block crystals, measured parallel to the surface, was 20-30 Å; it was 80-90 Å in the perpendicular direction. These block crystals had a columnar structure and occurred in a plane-stressed state. The microstress magnitude varied from 200 to 300 kg·mm⁻². Its origin was explained by the condensation process rather than by the deformation induced during separation of films from their base plates. Large microstresses were regarded as evidence of a high elastic deformation limit in the block crystals. This assumption was sustained by results of a direct load-testing of the film. TITLE: Investigation of the electric properties of monocrystalline silver films 27 1869

SOURCE: Fizika metallov i metallovedeniye, v. 21, no. 1, 1966, 150-152 68

TOPIC TAGS: metal film, silver, resistivity, electron scattering, galvanomagnetic effect B

ABSTRACT: This project, performed while B. T. Boyko was temporarily assigned to the Physics Department of the University of Virginia, deals with the variation in the resistivity of monocrystalline Ag films of a thickness of much below unity with respect to the free-path length of electrons. The resistivity of these films varies considerably with their thickness and this facilitates establishing the nature of electron scattering from the surface considering that previous studies have demonstrated that electrons are only specularly reflected from the surface of thin crystalline films of Bi, Au, Sn and Pb whose thickness is roughly equal to unity with respect to the free-path length of electrons and which thus display only limited variations in resistivity. The thin Ag films were prepared by vacuum-evaporating 99.999% pure Ag onto mica heated to 270-300°C (pressure $5 \cdot 10^{-8}$ torr). The rate of

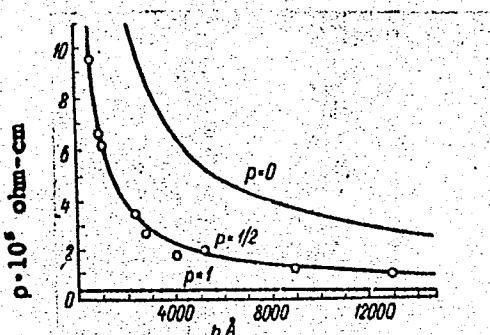

Fig. 1. Resistivity of Ag films as a function of film thickness. The curves show the theoretical variation in resistivity with thickness for $t = 31.2 \mu$ and $r_m = 600$; $p = 1$ - purely specular scattering; $p = 0$ - purely diffuse scattering.

ACC NR: AP6005149

Ag condensation was 4 Å/sec. The obtained films were monocrystalline with the (111) plane being parallel to the substrate and had a large number of twins and measured 20x5 mm in the substrate plane. Voltage drop on the films was measured at room and helium temperatures within two hours from the instant of removal of the film from the vacuum device, because otherwise the resistivity of Ag films at He temperature would increase at least 10% each day from the date of removal from the vacuum device (the nature of this phenomenon still has not been elucidated). Findings: by contrast with the data on Au films (Chopra, K. L., et al. J. Appl. Phys., 1963, 34, 1966) the ratio between the resistivities ρ of Ag films at room and helium temperatures $\frac{\rho}{\rho_{293^\circ\text{K}}/04.2^\circ\text{K}}$ varied from 17 to 175 with variation in film thickness h of from 640 to 13,000 Å. The free-path length l of electrons, extrapolated with respect to $r/h = 0$ is 31.2 μ; the slope of this curve yields $r_\infty = 1800$ (r_∞ is the ratio of resistivities at room and He temperatures for infinitely thick films); for $l = 31.2 \mu$ we have $r_\infty = 600$. At such a value of r_∞ , ρ (the portion of specularly reflected electrons) must be taken as 1/2, i.e. in this case one-half of the electrons is reflected specularly from the film and the other half, diffusely (Fig. 1). The fairly high resistivity ratio ($r_\infty = 600$) shows that these films are of satisfactory purity and thus can be used to investigate the influence of the dimensional effect on the galvanomagnetic properties of silver. "The authors wish to express their gratitude to Drs. R. Coleman and N. Cabrera for profitable discussion of this project." Orig. art. has: 2 figures, 1 formula.

TITLE: Production of thin films by evaporation in vacuum and by cathode sputtering in a gas discharge

SOURCE: AN UkrSSR. Fizika metallicheskikh plenok (Physics of metal films). Kiev, Naukova dumka, 1965, 40-58

TOPIC TAGS: metal film, polycrystalline film, epitaxial growth, crystal growth

ABSTRACT: The article consists of a survey of material reported at the Cleveland seminar on thin films (October 1963) and work done by the Metal-physics department of the Khark'kov Polytechnic Institute. A brief review is presented of two methods of thin-film production, evaporation in vacuum and cathode sputtering, and the main parameters influencing the formation of the condensate on the substrate are discussed. Topics dealt with are the apparatus used for evaporation and sputtering, the effect of aggressive gas impurities, apparatus used for the measurement of thin-film properties, the effect produced on the film by factors such as the substrate and its purity, the condensation rate, and the substrate temperature (and effective means for its control). It is deduced that cathode sputtering has certain advantages over evaporation in vacuum, especially when it is desired to produce pure single-crystal and poly-

TITLE: Electron diffraction study of the block structure of aluminum condensates

SOURCE: Fizika metallov i metallovedeniye, v. 21, no. 6, 1966, 848-853

TOPIC TAGS: aluminum, metal film, electron diffraction analysis

ABSTRACT: In an earlier paper, the authors described the electron diffraction micro-beam method for determining the size and disorientation of block crystallites in aluminum vacuum condensates 60-200 Å thick after annealing at 300° and above. In the present work, this technique was developed by increasing the resolution of the various reflections, so that the point diffraction lines on the electron diffraction patterns were obtained with films in the initial (unannealed) state. This made it possible to study the substructure of the films without altering it by the subsequent action of heat. The average length of the blocks in unannealed Al films condensed on an unheated substrate changes from 220 to 320 Å as the film thickness changes from 150 to 750 Å. The lower limit of the disorientation angles is 1.5-2°. Films 150 Å thick have a monoblock structure in their thickness. At 400 Å and higher, the monoblock character is impaired; it is probably a structural factor which determines the effect of the thick-

Cord 1/2

L 00739-67

ACC NR: AP6018942

ness on certain structurally sensitive properties. The presence of a sufficiently large number of blocks in the thickness of the film makes the latter similar to massive bodies. The density of the stream of condensing atoms is one of the parameters determining the form of the blocks, i. e., their size in the plane of the film and along the normal to it. Physical properties sensitive to the substructure may be different in the plane of the film and along the normal. Orig. art. has: 1 figure, 1 table, and 5 formulas.

TITLE: X-ray diffractometric investigation of the substructure of thin aluminum condensates

SOURCE: Fizika metallov i metallovedeniye, v. 22, no. 1, 1966, 73-77

TOPIC TAGS: diffractometer, x ray diffraction analysis, aluminum, metal vapor deposition / URS-50IM diffractometer

ABSTRACT: This work is a continuation of a previous investigation (Palatnik, L. S., et al. FMM, 1966, 21, 848), with the difference that it employs the x-ray diffractometric method to verify the possibility of differences between certain structurally sensitive physical properties in the plane of the thin film and along the normal with respect to this plane, which is assumed to be conditioned by different mechanisms of formation of regions of coherent scattering as a function of the condensation rate. To this end, 99.99% pure Al was vacuum-evaporated on two unheated glass substrates coated with NaCl and located at different distances

ACC.NR: AP6027788

O

from the evaporator. The mean condensation rate on one substrate was 7 \AA sec^{-1} and on the other substrate, 23 \AA sec^{-1} . The film obtained on the substrate closer to the evaporator was 1600 Å thick, while the film obtained on the more distant substrate was 500 Å thick. Packets of these films were then investigated with the aid of an URS-50IM diffractometer. Findings: for the thicker films (1600 Å), due to the higher condensation rate as compared with the thinner films (500 Å), the mean volume of regions of coherent scattering (r.c.s.) is greater, with the size of these regions increasing both in the plane of the film and at right angles thereto. Even so, however, the increase in film thickness becomes greater than the increase in the size of the r.c.s. in the direction normal to the film plane so that, after passing through some critical thickness, the formerly monocrystalline film now becomes polycrystalline in thickness. Orig. art. has: 1 figure, 2 tables.

TITLE: Elastic anisotropy of polycrystalline condensed films

SOURCE: AN SSSR. Doklady, v.167, no.1, 1966, 77-79

TOPIC TAGS: polycrystalline film, crystal anisotropy

ABSTRACT: The article describes electronographic studies of the deformation of thin polycrystalline films of aluminum, silver, and nickel, with thicknesses of 400-500 Å, condensed in a vacuum of 5×10^{-5} torr, at different temperatures of the support. The rate of condensation was 20-40 Å/sec. The films, separated from the support, were transferred to a plate with a slit and were put into the electronograph by means of a special device. Results of examination showed that, for thin polycrystalline vacuum condensates of the elastically anisotropic metals silver and nickel, the elastic anisotropy of the individual crystals was preserved, although not to the degree that might be expected for complete isotropy of the stress field, such as for example, for isolated mono-

crystals. For aluminum films with a weakly marked elastic anisotropy, anisotropic elastic deformations of the lattice were not observed electronographically. In nickel films, condensed at a temperature of 65°, the average size of the crystal blocks, observed by diffraction expansion, was 30 Å. Even with such a dispersed structure the elastic anisotropy of the individual blocks was preserved, but there was observed a tendency for it to become weaker in comparison with coarse grained films.

TITLE: A device for dropping parachute models. Class 62, No. 184629.

SOURCE: Izobret prom obraz tov zn, no. 15, 1966, 146

TOPIC TAGS: parachute, model test, test method

ABSTRACT: This Author Certificate introduces a device for dropping parachute models from captive balloons, kites, parachute towers, etc. It has a suspended container with safety pin bolts connected to the rip cord, the other end of the rip cord being fastened to the harness hitch. To carry out a massive parachute drop, the container has a row of compartments which are open in the bottom and spaced as desired. The container is suspended from a harness hitch by means of detachable tubing, so that the rip cord hangs loosely and the detachable tubing, which holds the container, is passed through a remotely controlled. Another version of the same device has a cutter made of a filament surrounding the tubing; this is heated by power source located at the control point. A swivel is inserted in the center of the harness hitch to prevent the entangling of the detachable tubing, the rip cord, and the restraining guard. Orig. art. has: 1 figure.

Illus. 4.

Examination of 42 preparations of lower extremities obtained from cadavers of adults showed that vascular and nervous branches on their way to the anterior muscles of the thigh go together, adjacent to each other and the relationship between them is rather constant. Muscular branches of the femoral nerve in their approach to every muscle are situated most frequently exteriorly and extero-anteriorly from the vascular branches which supply the corresponding muscle. Both the blood vessels and the nerves enter the medial edge of the muscles in the same zone, which for the majority of anterior muscles corresponds to adjacent areas of the medial third of the thigh. The place of entrance of the vascular and nervous branches into the vastus intermedius is situated mostly in its medial third. In choosing the most rational incisions it is necessary to take these facts into consideration. The general rule which may be recommended in approach to deep layers of the anterior part of the thigh by intermuscular planes is to take the external edge of the medially situated muscle as a landmark. However, if possible, one has to endeavour not to injure the spaces in the upper half of the thigh between the rectus femoris and vastus lateralis and intermedius where the most important vascular and nervous branches are situated.

Opistorchotic Hepatitis and Cirrhosis of
the Liver in Man

Orig Pub : Tr. Omskogo med. in-ta, 1957, No 22, 35-39

Abstract : The basic pathomorphological changes in
opistorchosis are expressed in subacute or
chronic productive-infiltrative angiocholitis
which leads to cirrhosis. Dystrophic changes
of liver parenchyma right up to necrosis of
whole complexes of liver cells are observed.
Regenerative processes are expressed in the

appearance of multinuclear epithelial cells and foci of nodular hyperplasia. In the interstitial tissue, manifestations of chronic inflammation with the appearance of lymphohistiocytic infiltrations were discovered, as well as leukocytes and eosinophils. Granulation tissue forms later and passes into scar tissue. The focal character of inflammatory and sclerotic changes in the liver, which develop in connection with involvement of bile ducts, is stressed. In 2 of 16 investigated cases, the affection of the liver in opistorchosis was diffuse. --

Title : The Problem of Neoplastic Growth in Human Opistorchosis.

Orig Pub : Tr. Omskogo med. in-ta, 1957, No 22, 40-44

Abstract : Among 84 persons who died from opistorchosis a primary cancer of the liver (cholangiocytic adenocarcinoma) was found in 6 (7.1%). The liver was enlarged; its weight was 1970-2750 grams; on its surface tubercular excrescences were noted corresponding to tumor nodules. There were cavities in which opisthorchis eggs were found. In the liver tissue there was the picture of chronic hepatitis and cirrhosis. In the bile ducts there was an inflammatory proliferation with marked atypicality of the

TITLE: Crystallization of gallium arsenide from supercooled melts

SOURCE: Ref. zh. Fizika, Abs. 4A624

REF. SOURCE: Sb. Simpozium. Protsessy sinteza i rosta kristallov i plenok poluprovodnik. materialov, 1965. Tezisy dokl. Novosibirsk, 1965, 3

TOPIC TAGS: gallium arsenide, crystallization, single crystal growth, supercooling

ABSTRACT: A study was made of the influence of different factors on the processes of crystallization of GaAs from stoichiometric melts: the degree of superheat of the melt, rate of cooling, the degree of supercooling, and the time of "isothermal soaking" in the supercooled state. The interrelationship between these parameters and the number of crystallization centers during the solidification of the melt is considered. The data obtained makes it possible to choose optimal conditions for the production of GaAs single crystals from melts, using "isothermal soaking" of the melts in the supercooled state. TITLE: Some Problems of Dump Car Construction (Nekotoryye voprosy dumpkarostroyeniya)

PERIODICAL: Gornyy Zhurnal, 1957, #10, pp 71-72 (USSR)

ABSTRACT: In order to transport large-lump ore and heavy rocks, dump cars with a 25-ton axle load must be constructed. Heavy dump cars with 6 and 8 axles have economical advantages.

In order to transport lighter freights, dump cars with enlarged volume capacity are expedient. The width of the existing dump cars can be increased; the height can also be increased by 200 to 300 mm.

Dump cars must be equipped with brakes of minimum dimensions. In particular, electropneumatic brakes should be tested.

The Kaliningrad RR Car Plant alone cannot handle the production of several dump car types. One additional plant for building dump cars is necessary. The expansion of the Kaliningrad Plant is not expedient.

AUTHORS: Bernadskiy, V.N.; Boyko, G.A.

TITLE: The Effect of External Cooling on the Quality of Joints in Roller Welding

PERIODICAL: Avtomaticheskaya svarka, 1960, No. 8, pp. 73 - 80

TEXT: A new external cooling method for the resistance seam welding process is described, consisting in water cooling for the contact rollers and compressed air blast over the welding area. Steel structure in the joints (photos, Fig. 5) has a lower content of hard components than structure produced with conventional external cooling, and the hardness of these components is lower, though the structure is naturally less uniformly fine-grained than after normalization. The new cooling decreases the cooling rate of a joint and causes a kind of heat treatment from inside by heat remaining in the metal after welding and separating additionally through the effect of the passing shunting current. The essence of the system is illustrated in a diagram (Fig. 2,6). One cooling device has been produced and installed in the welding stand of a flat folding tube mill (Fig. 7, photo). These tubes are produced from low-carbon rimming "08Kh" (08kp) steel and

Card 1/2

S/125/60/000/008/008/012
A161/A029

The Effect of External Cooling on the Quality of Joints in Roller Welding

welded continually in up to 300 m lengths on this special mill. Later, on the assembly site, the flat tubes are expanded by compressed air into round shape. A-bundant water cooling was used in the process and caused the formation of hard metal structure in the joints and deformation of the rollers. The new cooling system raises 1.3 to 1.6 times the mechanical strength of the joints. Engineer A.A. Trushchenko and the members of DTZ im. Lenina (DTZ im. Lenin) A.V. Toldayev, T.S. Shchegol', I.V. Alekseyeva and B.N. Parshin participated in the development of the system. There are 9 figures, 3 tables and 5 Soviet references.

TITLE: Spontaneous cleaning of oxide films from metal surfaces

SOURCE: AN SSSR, Doklady*, v. 159, no. 1, 1964, 72-73

TOPIC TAGS: carbon steel, chromium nickel steel, air oxidation,
oxide film, spontaneous film disappearance, steel self-cleaning

ABSTRACT: Oxide films were observed to disappear spontaneously from the surfaces of many steels and alloys to which the air had been admitted. Thus, oxide films on the surfaces of various steels and also on aluminum foil completely disappeared after the container was heated to 1300°C for several minutes. A similar self-cleaning tendency was observed on carbon- or Cr-Ni-steel foil placed in such a container. The air pressure inside the container at first rises during the heating process and then drops abruptly to approach zero.

Card 1/2

L 32013-65

ACCESSION NR: AP4049134

where it remains almost unchanged. It is difficult, as yet, to give an exact theoretical explanation for the phenomenon. It can be assumed that at a high temperature the reaction of the metal with oxygen or oxide film on a solid metal is faster than the diffusion of oxygen through the film. In the form of oxides and nitrides on the metal's surface. The authors recommend a further study of this phenomenon. At present it is used in various fusionless welding methods for surfaces of the metal, in the production of bimetallic parts by hot descaling, etc. Orig. art. has: 3 figures.

method

ABSTRACT: Author Certificate No. 164090 has been issued for a new method of temperature control for metal parts heated in vacuum developed at the Electric Welding Institute im. Ye. O. Paton. The temperature of the part being heated is indicated by the value of the thermionic emission current in the circuit formed by the part being heated (the cathode) and another metal plate at a positive potential relative to the cathode (the anode) located near the cathode in the vacuum chamber. With an unchanging heated area, anode potential, interelectrode gap, and vacuum, the emission current unambiguously depends on the temperature of the metal part being heated. The emission current is easily registered and is much stronger than the current obtained

from a thermocouple or an optical temperature sensor. For example, in vacuum diffusion bonding of stainless steel parts, the current reached 2-3 mamp at the source voltage of 100 v. Under the experimental conditions, the temperature measurement accuracy was $\pm 12-16^\circ\text{C}$. The new method of temperature control is contactless, which makes it possible to recommend it for various technological operations requiring heating and manipulation of parts in vacuum in mass production. TITLE: Method of producing metal laminates. Class 7, No. 177824 [announced by the Electric Welding Institute im. Ye. O. Paton (Institut elektrosvarki)]

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 2, 1966, 13

TOPIC TAGS: metal, clad metal, metal laminate, metal rolling

ABSTRACT: This Author Certificate introduces a method of producing metal laminates by pack rolling with a low-melting vanishing insert placed between the metals to be bonded. To obtain a strong bond between dissimilar metals, the rolling is done with the insert in the liquid state. [ND]

Orig. Pub. : Sad i ogorod, 1957, No. 7., 73

Abstract : A mid-season maturing local cucumber variety, Margelanskiy 822, improved at the Uzbek Vegetable Potato Station has distinguished itself in particular at the Stalinabad Vegetable Variety Plot. The fruits are 185-230 g, cylindrical, 15-18 cm long, smooth, glossy, dark green, with long white stripes, and do not turn yellow for a long time. The gustatory and salt qualities are good. It yielded 640 cwt/ha. in 1956. It is districts in the Tadzhik and Uzbek SSR. In preliminary trials

TITLE	: A Method of Growing Vegetable Crops Without Transplanting.
ORIG. PUB.	: Sad i ogorod, 1958, No. 3, 13-15.
ABSTRACT	: On Stalinsbad variety trial plot, with the direct method of growing tomatoes, peppers and eggplant by sowing the seeds into the ground simultaneously with the transplanting of the seedlings, marketable ripeness came only 5-7 days later than that of the transplanted crop over a period of 3 years (1955-1957). When sowing the seeds into the ground 8-10 days earlier than the date of transplanting the seedlings, the ripening took place simultaneously. With the direct method of the cultivation, the plants had deep roots, tolerated the drought better, re-
